Emmanuel A. Cereno

Assignment 2

1. Data. Raw, unorganized symbols, numbers, characters or facts collected for reference or analysis
- In computing, data represents raw values stored in memory cells. Unprocessed data lacks context; algorithms process and transform raw data into structured information.

2. Data structures - A specialized layout, scheme, or organization format for storing, arranging and managing in computer memory.
- it determines how data elements relate to one another and directly dictates the speed and memory consumption of operations

3. Abstract Data Types (ADT's) - High level mathematical model for a data type that is defined entirely by its theoretical behavior and allowable operations
- ADT specifies what operations can be performed

4. Algorithms - step by step set of computational rules or instructions designed to solve a specific problem.
- Algorithm manipulate data stored within data structures.
